## Freeze-dried food

## **Detail Introduction :**

Fruits and vegetables provide people with nutrients such as vitamins. In order to extend the shelf life foods, people have developed, sun-dried, dried, pickled, and canned fruit methods, but like vitamins, have poor ability to withstand high temperatures. Once it encounters high temperatures, it will suffer losses. Therefore, people who are full of wisdom have developed a low-temperature processing tech freeze-drying technology.

Freeze-dried food is loose in structure, easy to absorb moisture in the air, and can be restored to its o state after absorbing water, so after freeze-drying, pay attention to the packaging, usually in vacuum nitrogen storage, If the freeze-dried food you buy does not have the above preservative measures, it come into contact with oxygen in the air, and it will rot in a relatively short period of time like before f drying. Therefore, it is recommended to eat it as soon as possible after opening, Or vacuum, seal and in the refrigerator.

But as long as it is freeze-dried and stored with nitrogen, it can be stored for a long time without ope package. Take dried apples as an example, the shelf life of dried apples filled with nitrogen after freez can be as long as 18 months.
